Variational Analysis in Pressure Coordinates

1. The variational integral and constraint

The idea is to explicitly introduce some form of balance equation as a constraint on hemispheric or global analyses. In particular, the Flattery type of analysis ignores the nonlinear relation between wind and geopotential found in the gradient wind relation or in the balance equation. We can do this by means of a variational analysis, following the ideas of Sasaki (J. Met. Soc. Japan, 1958, vol. 36, No. 3, pp. 1-88) and Stephens (J. App. Meteor., 1970, vol. 9, pp. 737-739). In this procedure, we change an initial analysis of geopotential and streamfunction, denoted by $\phi^o$ and $\psi^o$, to a final analysis $\phi^f$, $\psi^f$:

$$\phi^f = \phi^o + \phi', \quad \psi^f = \psi^o + \psi'. $$

The final fields satisfy a dynamic constraint and the spatially integrated squares of $\phi'$ and $\psi'$ are minimized.

Consider K pressure surfaces at which $\phi$ and $\psi$ are given, $k = 1, \ldots, K$. We can form K-1 "temperatures"

$$T_k = \zeta_k (\phi_k - \phi_{k-1}), \quad k = 2, \ldots, K$$

$$\zeta_k = \left[ R \ln \left( \frac{p_{k-1}}{p_k} \right) \right]^{-1}. $$

As the constraint, we take the balance equation

$$\nabla^2 \phi - \nabla \cdot (f \nabla \psi) + \nabla \cdot \left[ \frac{1}{2} \nabla (\nabla \psi)^2 - \nabla^2 \psi \nabla \psi \right] = 0, $$

(1.2)
and linearize it to the extent of evaluating the nonlinear term only with the original streamfunction $\psi^0$. Thus

$$\nabla^2 \phi' - \nabla \cdot \nabla \psi' + \nabla \cdot A^0 = 0,$$

$$A^0 = \nabla \phi^0 - \nabla \psi^0 + \frac{1}{2} \nabla (\nabla \psi^0)^2 - \nabla \nabla \phi^0 \nabla \psi^0. \quad (1.3)$$

$\nabla \cdot A^0$ is a known quantity, measuring the extent to which $\psi^0$ and $\phi^0$ do not satisfy (1.2).

The variational problem is set up now as the problem of minimizing the area integral of

$$I = \sum_{k=1}^{K} \gamma_k \left( \nabla \psi_k' \right)^2 + \sum_{k=2}^{K} \beta_h \left( \psi_k' \right)^2 + \alpha \left( \phi' \right)^2$$

$$+ \psi \sum_{k=1}^{K} \left[ \nabla^2 \phi_k' - \nabla \cdot \nabla \psi_k' + \nabla \cdot A_k^0 \right]. \quad (1.4)$$

In this expression $\psi_k' = \gamma_k (\psi_k' - \phi_{k-1}')$, and the variables $\alpha = \alpha (x, y)$, $\beta = \beta (x, y, \phi)$, and $\gamma = \gamma (x, y, \phi)$ are positive analysis weights. $p (x, y, \phi)$ is a Lagrange multiplier (as yet unknown). The weights $\alpha$, $\beta$ and $\gamma$ are set inversely proportional to the assumed error in the corresponding original fields

$$\alpha \propto (\delta \phi^0)^{-2},$$

$$\beta \propto (\delta \psi^0)^{-2},$$

$$\gamma \propto (\delta \psi^0)^{-2}. \quad (1.5)$$
For example, a highly accurate \( T^0 \) field corresponds to a small \( \delta T^0 \), a large \( \beta \), and a tendency to keep \( T' \) small in the process of minimizing (1.4).

Before passing on to the variational details, it can be pointed out that the brutal step of ignoring \( \psi' \) in the vector \( \underline{A} \) of (1.3)—which avoids the usual balance equation ellipticity problem—can be softened somewhat if desired by iterating the entire analysis cycle one or more times with \( \psi^0 \) and \( \phi^0 \) replaced by successive values of \( \phi^f \) and \( \psi^f \).

2. Variational algebra

Let \( \delta \) denote changes in \( \phi'_i \). The corresponding change in \( I \) is twice

\[
[-\beta_2 T'_2 \zeta_2 + \alpha \phi'_i] \delta + \rho_i \nabla^2 \delta
= \left[-\beta_2 \zeta_2 (\phi'_2 - \phi'_1) + \alpha \phi'_i + \nabla^2 \rho_i\right] \delta + \nabla \left[ \rho_i \nabla \delta - \delta \nabla \rho_i \right].
\]

The divergence term integrates out on the sphere. On the Northern Hemisphere it vanishes if, at the equator,

I) \( \rho_i = 0 \) and \( \delta \phi'_i = 0 \), \hspace{1cm} (2.1a)

or,

II) \( \partial \rho_i / \partial \theta = 0 \) and \( \phi(\delta \phi'_i) / \partial \theta = 0 \). \hspace{1cm} (2.1b)

An extremum with respect to \( \delta \phi'_i \) therefore requires that

\[
(\alpha + \beta_2 \zeta_2) \phi'_i - \beta_2 \zeta_2 \phi'_2 + \nabla^2 \rho_i = 0.
\]
Now let δ denote changes in \( \phi_k' \), \( k = 2, \ldots, K \). Calculations similar to those above lead to

For \( k = 2, \ldots, K-1 \):

\[
- \beta_k \nabla^2 \phi_{k-1}' + (\beta_k \nabla^2 + \beta_{k+1} \nabla^2) \phi_k' - \beta_{k+1} \nabla^2 \phi_{k+1}' + \nabla^2 \rho_k = 0. \tag{2.2b}
\]

For \( k = K \):

\[
- \beta_k \nabla^2 \phi_K' + \beta_K \nabla^2 \phi_K' + \nabla^2 \rho_K = 0, \tag{2.2c}
\]

with boundary conditions equivalent to (2.1) on \( \rho_k \) and \( \delta \phi_k' \).

Finally, let δ denote a variation in \( \psi_k' \). The corresponding variation of I is twice

\[
\nabla \phi_k \cdot \nabla \delta - \rho_k \nabla \cdot \nabla \delta =
\]

\[
= - [\nabla \cdot (\nabla \phi_k') + \nabla \cdot f \nabla \rho_k] \delta
\]

\[
+ \nabla \cdot [\beta_k \nabla \psi_k' + f (\delta \nabla \rho_k - \nabla \cdot \delta)]
\]

The divergence term disappears on integration for the globe. If we treat only the Northern Hemisphere, its vanishing requires at the equator,

I) \( \partial \psi_k' / \partial \theta = 0 \), \( \tag{2.3a} \)

or,

II) \( \delta \psi_k' = 0 \) \( \tag{2.3b} \)

leaving the equation

\[
\nabla \cdot \beta_k \nabla \psi_k' + \nabla \cdot f \nabla \rho_k = 0. \tag{2.4}
\]
Equations (2.2a), (2.2b), (2.2c), (2.4) and the balance equation (1.3) constitute the system of 3K equations to determine $\psi'$, $\phi'$, and $\rho$ at $k = 1, \ldots, K$ given a knowledge of $\alpha$, $\beta$, $\gamma$ and $\nabla \cdot \mathbf{A}^o$.

When the Northern Hemisphere alone is considered, the set of equatorial boundary conditions in (2.1b) and in (2.3b) are most suitable, since $\psi$ as an odd function of latitude and $\phi$ as an even function of latitude is most realistic. In this case $\rho$ is an even function also as far as the boundary condition (2.1) is concerned. For simplicity and definiteness we can in the hemispheric case consider

$\phi, \rho, \alpha, \beta, \gamma$ as even functions of latitude, and

$\psi$ as an odd function.

The balance equation (1.3) is consistent with these and poses no further restriction (except that the hemispheric integral of $\nabla \cdot \mathbf{A}^o$ vanish).

Equations (2.2a)-(2.2c), when integrated over the hemisphere, place constraints on hemispheric integrals of $\beta_k \phi_k'$:

$$\iint \beta_k \phi_k' \, d\text{hem} = 0$$

(2.6)

Hemispheric integration of (2.4) shows that the line integral

$$\int_0^{2\pi} \left[ \nabla \cdot \mathbf{A}^o \right] \, d\gamma = 0.$$  

(2.7)
If \( N_h \) were independent of longitude at the equator, this would be equivalent to constraining the horizontally averaged vorticity to be preserved:

\[
\iiint \nabla \psi \, dh \, d\xi = \int \left( \frac{\partial \psi}{\partial \Theta} \right) \, d\Theta. \tag{3.1}
\]

3. Separation of variables

A considerable step toward making solution of the set (1.3), (2.2a)-(2.2c), and (2.4) tractable is to simplify the distribution of analysis weights. We shall assume

\begin{align*}
\alpha(n,y) &= 2 \text{ times } \beta'(n,y), \\
\beta(n,y,p) &= \overline{\beta_k} \text{ times } \beta'(n,y), \\
\gamma(n,y,q) &= \overline{\gamma_k} \text{ times } \gamma'(n,y),
\end{align*}

where the horizontal functions are nondimensional and positive.

To arrive at this specification, define

\begin{align*}
k = 1: & \quad \gamma_1 = \frac{p_1 - p_2}{2 \, (\delta u_h^0)^2}, \\
k = 2, \ldots, K: & \quad \gamma_k = \frac{p_{k-1} - p_{k+1}}{2 \, (\delta u_h^0)^2}, \\
\beta_k &= \frac{p_{k-1} - p_k}{(\delta T_h^0)^2},
\end{align*}

where the numerators express a weighting with the pressure thickness associated with the wind and temperature values (\( p = \text{press(mb)} \div 1000 \)).
Given these three-dimensional fields we choose $\bar{\mathbf{v}}_k$ and $\bar{\beta}_k$ to be the horizontal averages of (3.2), and define $\mathbf{v}'$ and $\beta'$ by

$$
\mathbf{v}'(\nu, \eta) = K^{-1} \sum_{k=1}^{K} \left( \mathbf{v}_k / \bar{\mathbf{v}}_k \right),
$$

$$
\beta'(\nu, \eta) = (K-1)^{-1} \sum_{k=2}^{K} \left( \beta_k / \bar{\beta}_k \right).
$$

For $\alpha$, we first define a field

$$
\alpha = \frac{(\bar{\mathbf{v}} - \bar{\mathbf{v}}_2)}{(\mathbf{\varepsilon} \mathbf{\phi}^0)^2},
$$

where $\mathbf{\varepsilon} \mathbf{\phi}^0(\nu, \eta)$ is the analysis error in $\mathbf{\phi}^0$ at $k = 1$. $\bar{\alpha}$ is obtained then by

$$
\bar{\alpha} = \text{spatial average of } \left( \alpha / \beta' \right)
$$

(3.4b)

$(\delta \eta)^2$ and $(\delta T)^2$ vary by a factor of about 10 from data-rich areas to the data-poor oceanic areas which occupy most of the area. $\mathbf{v}'$ and $\beta'$ will therefore vary from a minimum of (say) 0.2 over the oceans to 2 or 3 over the continents, but will each have a horizontal average of one.

If $\alpha$ in (3.4a) were equated to $\beta_2$, we would have $\mathbf{\varepsilon} \mathbf{\phi}_1 = R \delta T_2 (\mathbf{v} / \mathbf{v}_2)$. $\mathbf{\varepsilon} \mathbf{\phi}_1$ is also equivalent to $(RT/p)$ times $\delta p$ (sea-level). For $p_1 = 1$ and $p_2 = 0.85$, a $\delta T_2$ of 0.6 deg corresponds to $\mathbf{\varepsilon} \mathbf{\phi}_1 = 26.6 \text{ m}^2\text{sec}^{-2}$ and $\delta p(\text{sea level}) = 0.34 \text{ mb}$. We may therefore expect approximate equality of $\bar{\alpha}$ with $\bar{\beta}_2$, since 0.6 deg and .34 mb are both realistic for good analysis regions.

It is convenient to change to nondimensional variables and operators at this point, using the radius of the earth $(a)$ and $(1/2\Omega)$ ($\Omega$ = the earth's angular velocity) as the length and time units. To be specific we set...
Nondimensional        Dimensional

\[ \phi_k = \phi_k' \sqrt{\frac{f_k}{L}} / 2 \alpha \]
\[ \psi_k = \psi_k' \sqrt{\frac{f_k}{L}} / \alpha \]
\[ r_k = \rho_k' \frac{2 \alpha}{\sigma \sqrt{f_k}} \]
\[ \nabla = \alpha \nabla \]

The square roots of \( \sqrt{f_k} \) are introduced to produce symmetry of the matrix \( B_k \) in (3.6c) below.

Equation (1.3) becomes
\[ \nabla^2 \phi_k - \nabla \sin \theta \nabla \psi_k = - (\alpha \sqrt{f_k} / 2 \Omega) \nabla \psi_k^0 = - A_k. \] (3.6a)

Equation (2.4) becomes
\[ \nabla \cdot \frac{\partial}{\partial t} \nabla \psi_k + \nabla \sin \theta \nabla r_k = 0. \] (3.6b)

The \( K \) equations (2.2a), (2.2b), and (2.2c) become
\[ \nabla^2 r_k + \beta' \sum_{L=1}^{K} B_{Lk} \phi_L = 0. \] (3.6c)
is the symmetric tri-diagonal matrix

\[
B_k \begin{pmatrix}
    d_1 & -a_2 & 0 & 0 \\
    -a_2 & d_2 & -a_3 & 0 \\
    0 & -a_3 & d_3 & -a_4 \\
    \vdots & \vdots & \vdots & \ddots & \vdots \\
    0 & \vdots & \ldots & \ldots & -a_{k-1} & d_{k-1} & -a_k \\
    0 & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & 0
\end{pmatrix}
\]  

(3.7)

in which the diagonal terms are

\[
d_1 = \frac{4. \alpha^2 a^2 (\overline{\lambda} + \overline{\beta} \bar{\tau}_2^2)}{\bar{\tau}_1},
\]

\[
d_{h=2, \ldots, k-1} = \frac{4. \alpha^2 a^2 (\overline{\beta} \bar{\tau}_h^2 + \overline{\alpha} \bar{\tau}_h^2)}{\bar{\tau}_h},
\]

\[
d_k = \frac{4. \alpha^2 a^2 \overline{\beta} \bar{\tau}_k^2}{\bar{\tau}_k},
\]

(3.8a)

and the off-diagonal terms are

\[
a_{h=2, \ldots, k} = 4. \alpha^2 a^2 \overline{\beta} \bar{\tau}_h^2 (\bar{\tau}_h \bar{\tau}_{h-1})^{-1/2}
\]

(3.8b)

\(B_k\) has \(K\) positive eigenvalues \(\lambda_j\) and orthogonal eigenvectors \(e_{kj}\): 

\[
\sum_h B_{kh} e_{kj} = \sum_h B_{kh} e_{kj} = \lambda_j e_{lj},
\]

\[
\sum_h e_{kj} e_{kl} = \delta_{j,l}
\]

(3.9)

\(\sqrt{It\text{ can be shown that}}\)

\[
\lambda_j \sum_{k=1}^{K} \bar{\tau}_k f_k^2 = 4. \alpha^2 a^2 \left[ \bar{\lambda} + \sum_{k=2}^{K} \overline{\beta} \bar{\tau}_k^2 (f_k - f_{k-1})^2 \right]
\]

where

\[
f_k = e_{kj} (\bar{\tau}_k)^{-1/2}
\]
We expand in these eigenvectors:

\[
(H_j, S_j, R_j, F_j) = \sum_k e_{kj}(\phi_k, \psi_k, \gamma_k, A_k),
\]

(3.10a)

\[
(\phi_k, \psi_k, \gamma_k, A_k) = \sum_j e_{kj}(H_j, S_j, R_j, F_j).
\]

(3.10b)

Equations (3.6a)-(3.6c) now become a set of \(K\) independent two-dimensional problems \((j = 1, \ldots, K)\):

\[
\nabla^2 H_j - \nabla \cdot \sin \theta \nabla S_j = -F_j,
\]

(3.11a)

\[
\nabla \cdot \theta' \nabla S_j + \nabla \cdot \sin \theta \nabla R_j = 0,
\]

(3.11b)

\[
\nabla^2 R_j + \beta' \lambda_j H_j = 0.
\]

(3.11c)

These are the equations which must be solved in the horizontal coordinates. Variable coefficients on the left side consist of \(\sin \theta\), \(\theta'\), and \(\beta'\), \(\lambda_j\) being a constant for each \(j\).

Table I shows the values of \(\lambda_j\) and \(e_{kj}\) which exist for the case in which the \(K\) pressure levels are those of the 12 standard pressure levels \(p = 1.0, 0.85, 0.7, 0.5, 0.4, 0.3, 0.25, 0.2, 0.15, 0.1, 0.07, \) and 0.05, with uniform values at all \(k\) of \((\delta T)^2 = (0.6 \text{ deg})^2\) and \((\delta v)^2 = (2.5 \text{ m sec}^{-1})^2\), and with \(\delta \phi_j\) equal to 26 \(m^2\text{sec}^{-2}\). (These values are probably typical of analysis errors in data-rich regions.)
Table I. Values of $\lambda_j$ and $e_{kj}$ for 12 standard pressure levels. $(\delta T)^2 = (0.6 \, \text{deg})^2$, $(\delta v)^2 = (2.5 \, \text{m sec}^{-1})^2$ and $(\delta \phi_1)^2 = (26 \, \text{m}^2\text{sec}^{-2})^2$. Computed with double precision arithmetic on an IBM 360/195, but $e_{kj}$ values are truncated for brevity.

</table>
The determinant of $B_{kl}$ is readily shown to equal

$$det B_{kl} = (2\pi \alpha)^{2k} \frac{\overline{t_j t_k^2 \cdots \overline{t_k t_k^2 \cdots}}}{\overline{r_j r_k r_k^2 \cdots}}$$

Setting $\alpha$ equal to zero—equivalent to ignoring $\alpha (\phi_j')^2$ in the integrand (1.4)—would therefore introduce one zero value for $\phi_j$

This solution in (3.11) has zero $R_j$ and $S_j$—showing that all adjustment in (3.11a) for this degenerate mode occurs in the geopotential field $H_j$. The corresponding eigenvalue $\epsilon_{k_j}$ is equal to $(\overline{r_k} / \Sigma \delta_k)^{1/2}$.

$\lambda_j$ in Table I evidently acts as the square of a vertical wave number, since the number of sign changes in each eigenvector increases steadily from zero to eleven as $\lambda_j$ increases monotonically with $j$.

The last eigenvector is unique in its rapid fall off in magnitude for $k > 1$. To the extent that it resembles a delta function $\delta_{k,1}$, it implies that equations (3.11) could almost be written directly for $\phi_k$, $\psi_k$, $r_k$ and $h_k$ at level $k = 1$, with $\lambda_j = \lambda_{12}$. This isolation seems undesirable. In this example $\delta_{k,1}$ was chosen to correspond to a somewhat optimistic sea-level pressure error of only $1/3$ mb. Larger values of $\delta_{k,1}$ (smaller $\alpha$) will reduce the semi-isolation of layer $k = 1$ that is present in Table I, and should be considered carefully.

The set of equations (3.11) is easily manipulated into the following relation

$$\gamma' (\alpha S)_j^2 + \beta' \lambda_j H_j^2 = R_j F_j + \nabla \left[ \sin \theta (S \theta - R \theta S)_j + \gamma' S \theta S + R \theta H - H \theta R \right]$$  (3.12)
showing that the horizontally integrated modal squared amplitude is determined by the horizontal average of RF. The equivalent statement for the original variables $\psi'$ and $\phi'$ is best derived from (1.3), (2.2a), (2.2b), (2.2c), and (2.4). This can be done without the separation assumption (3.1) for the weights $\alpha$, $\beta$, $\gamma$. (2.4) is multiplied by $-\psi_k'$ and (1.3) is multiplied by $\rho_k$ to produce, for each $k$, the relation

$$
\nu_k (\nabla \psi_k')^2 - \phi_k' \nabla^2 \rho_k = \rho_k \nabla \cdot \mathbf{A}^o_k
$$

$$
+ \nabla \cdot \left[ f (\psi' \nabla \rho - \rho \nabla \psi') + \gamma \psi' \rho' + \rho \psi' \phi' - \phi' \rho' \right]_k .
$$

If $\mathbf{b}_k$ temporarily denotes $\beta_k \psi_k^2$, equations (2.2a), (2.2b) and (2.2c) can be manipulated into the form

$$
- \phi_k' \nabla^2 \rho_k = - \phi_k' \left[ \mathbf{b}_2 (\psi_k' - \phi_k') - \alpha \phi_k' \right],
$$

$$
- \phi_k' \nabla^2 \rho_k = - \phi_k' \left[ \mathbf{b}_{k+1} (\psi_k' - \phi_k') - \mathbf{b}_k (\psi_k' - \phi_{k-1}) \right] \quad (k = z, \ldots, k-1),
$$

$$
- \phi_k' \nabla^2 \rho_k = \phi_k' \left[ \mathbf{b}_k (\psi_k(3.14)

When these are introduced into (3.13) and the result summed over $k$, we obtain

$$
\sum_{k=1}^{K} \nu_k (\nabla \psi_k')^2 + \alpha (\phi_k')^2 + \sum_{k=2}^{K} \beta_k (\phi_k')^2
$$

$$
= \sum_{k=1}^{K} \rho_k \nabla \cdot \mathbf{A}^o_k + \mathbf{D}_k
$$

where $\mathbf{D}_k$ indicates a collection of $\nabla \cdot$ terms which disappear on horizontal integration. This equation, like its specialized modal counter-
part (3.12), shows how the Lagrange multiplier $p$ implicitly, through its organization with respect to $\nabla^2 A^0$, acts to determine the resulting minimum integrated value of the original integrand (1.4).

4. Response to a localized distribution of $\nabla^2 A^0$

The nature of the solutions of (3.10) and (3.11) can be investigated under certain simplified conditions. The most fruitful simplification is to treat $\sin \theta$ as a constant in (3.11). At the same time, let us for convenience define

$$
\begin{align*}
\phi_j &= H_j, \\
\alpha_j &= \sin \theta S_j, \\
\nu_j &= \sin^2 \theta R_j, \\
\sigma_j &= \sin \sqrt{\lambda_j}.
\end{align*}
$$

(4.1)

(3.11) then becomes

$$
\begin{align*}
\nabla^2 \phi_j - \nabla^2 \alpha_j &= - F_j, \\
\nabla \phi_j \nabla \phi_j + \nabla^2 \nu_j &= 0, \\
\nabla^2 \nu_j + \beta \sigma_j^2 \phi_j &= 0.
\end{align*}
$$

(4.2)

We will use these, in combination with (3.10), to discuss two effects. Effects of irregularities in $\beta'$ and $\nu'$ are discussed in section 5. In this section we determine the response to a localized "point source" of
the forcing function $\nabla \cdot A^0$. We do this under the further assumption that $\beta = \gamma = 1$. Equations (4.2) then reduce to

$$
\nabla^2 h_j - \nabla^2 z_j = -F_j,
$$

$$
\nabla^2 z_j - \sigma_j^2 z_j = 0,
$$

(4.3)

which combine into

$$
\nabla^2 h_j - \sigma_j^2 h_j = -F_j.
$$

(4.4)

We see already that the equation for each $j$ has associated with it a characteristic length $L_j$. In dimensional units this is

$$
L_j = \frac{a}{\sigma_j} = \frac{a}{\sin \theta \sqrt{\beta_j}}.
$$

For $\sin \theta = 0.707$, the eigenvalues of Table I produce values of $L_j$ ranging from $L_{12} = 50$ km to $L_1 = 868$ km. In other words, the highly oscillatory vertical structure represented by $e_{k12}$ in Table I, if excited at a particular horizontal location $(x_0, y_0)$, will disappear rapidly with distance horizontally from $(x_0, y_0)$. The smooth vertical field $e_{k1}$ in Table I, however, will extend considerably further in the horizontal. This arrangement of response seems desirable and suggests that the form for $I$ in (1.4) is satisfactory.
We consider now the circulatory symmetric case (with \( x \) denoting the radial coordinate) produced by

\[
\begin{align*}
0 & \leq \nu < \nu_0 : \quad F_j = F_{j_0} = \text{constant} \\
\nu_0 < \nu \leq \infty : \quad F_j = 0.
\end{align*}
\]  

(4.5)

The differential equation is

\[
\frac{1}{\nu} \frac{d}{d\nu} \left( \nu \frac{d}{d\nu} h_j \right) - \sigma_j^2 h_j = - F_j,
\]

and the solution that maintains continuity of \( h_j \) and \( \partial h_j / \partial \nu \) at \( \nu = \nu_0 \), and which disappears as \( \nu \to \infty \), is

\[
\begin{align*}
\nu < \nu_0 : \quad h_j &= \left[ 1 + U_j(\nu) \right] F_{j_0} / \sigma_j^2 \\
\nu > \nu_0 : \quad h_j &= W_j(\nu) F_{j_0} / \sigma_j^2
\end{align*}
\]

(4.6a)

where

\[
\begin{align*}
U_j(\nu) &= - \sigma_j^2 K_1(\sigma_j \nu_0) I_0(\sigma_j \nu), \\
W_j(\nu) &= \sigma_j^2 I_1(\sigma_j \nu_0) K_0(\sigma_j \nu).
\end{align*}
\]

(4.6b)

\( I_0, I_1, K_0 \) and \( K_1 \) are the modified Bessel functions described on pages 374-379 of Abramowitz and Stegun (1964). \( U_j \) is negative with a maximum magnitude of 1 at \( \nu = \nu_0 \), \( \sigma_j \nu_0 \to 0 \). \( W_j \) is positive. Its maximum value (reached at \( \nu = \nu_0 \)) increases from 0 to 0.5 as \( \sigma_j \nu_0 \) varies from 0 to \( \infty \). The general character of the solution (4.6a) is a simple bell-shaped curve, having a discontinuity in \( d^2 h / d\nu^2 \).

Let us define the original forcing function as having the special form

\[ \frac{\nabla \cdot A}{f^2} = \text{constant} = \left[ \frac{(\nabla \cdot A^0)}{f^2} \right] \text{center} \]  

for \( \mathcal{M} \leq \mathcal{M}_0 \) at one level, \( k = l \), zero everywhere at all other levels and also zero at level \( \ell \) for \( \mathcal{M} > \mathcal{M}_0 \). If \( \nabla^2 \psi^0 + \frac{1}{f^2} \nabla \cdot A^0 \) has the order of magnitude \((\text{velocity/horizontal scale length})^2\) and it will tend to be negative in cyclonic flow, positive in anticyclonic flow. We might expect (4.7) to be as large as \(-0.25^2\) at the tropopause in a major middle-latitude trough region, and perhaps even closer to one in magnitude in sharp curved jets.

From (3.10b) and (3.6a) we then find that

\[ F_j (\mathcal{M} > \mathcal{M}_0) = 0, \quad (4.8) \]

\[ F_j (\mathcal{M} < \mathcal{M}_0) = F_{j0} = \frac{f^2 \mathcal{M}_0}{2\Omega} \varepsilon_{l_j} \left( \frac{\nabla \cdot A^0}{f^2} \right)_0 \]

For \( \mathcal{M}_0 \rightarrow 0 \), \( \mathcal{W}_j \rightarrow \frac{1}{2} (\Omega \cdot \mathcal{M}_0)^2 k_0 (\Omega \cdot \mathcal{N}) \), suggesting an alternate formulation in which \( F_{j0} \mathcal{M}_0^2 \) is kept fixed, but \( \mathcal{M}_0 \) is set equal to zero:

\[ \mathcal{H}_j = \frac{1}{2} \left[ F_{j0} \mathcal{M}_0^2 \right] k_0 (\Omega \cdot \mathcal{N}), \quad 0 < \mathcal{N} \leq \infty. \]

This has a logarithmic singularity at \( \Omega \cdot \mathcal{N} \rightarrow 0 \). This is a true "point source," but seems less satisfactory for a quantitative interpretation.
where our choice of the single level at which \( \nabla \cdot \mathbf{A}^0 \) is not zero prescribes the value of \( l \). This is consistent with (4.5).

As measures of the response to this localized forcing, we first consider the change in geostrophic vorticity and the change in actual vorticity, both nondimensionalized through a division by \( f \). We first find, at level \( k \), that

\[
\frac{1}{f^2} \nabla_{\text{dim}}^2 (\phi^f - \phi^0) \bigg|_k = \frac{2 \pi}{\alpha f^2 \sqrt{f_k}} \sum_j e_{kj} \nabla^2 \phi_j^0,
\]

\[
\frac{1}{f^2} \nabla_{\text{dim}}^2 (\psi^f - \psi^0) \bigg|_k = \frac{2 \pi}{\alpha f^2 \sqrt{f_k}} \sum_j e_{kj} \nabla^2 \psi_j^0.
\]

(\( \nabla^2 \) is dimensional on the left side, nondimensional on the right side.)

Using (4.3), (4.6), and (4.8), we obtain

\[
\frac{1}{f^2} \nabla_{\text{dim}}^2 (\phi^f - \phi^0) \bigg|_k = \left( \frac{y_k}{y_h} \right)^{\frac{4}{3}} \left( \frac{\nabla \cdot \mathbf{A}^0}{f^2} \right)_{\text{center}} \sum e_{kj} \psi_j (U_j, W_j),
\]

\[
\frac{1}{f^2} \nabla_{\text{dim}}^2 (\psi^f - \psi^0) \bigg|_k = \left( \frac{y_k}{y_h} \right)^{\frac{4}{3}} \left( \frac{\nabla \cdot \mathbf{A}^0}{f^2} \right)_{\text{center}} \sum e_{kj} \psi_j (U_j, W_j)
\]

in which the first term in the parenthetical expression is used for \( \mathcal{N} < \mathcal{N}_0 \), and the second for \( \mathcal{N} > \mathcal{N}_0 \). The subscript "center" on \( \nabla \cdot \mathbf{A}^0 \) is a reminder that it is the constant value assumed for \( \mathcal{N} < \mathcal{N}_0 \) at level \( k \).

These expressions are most easily interpreted if we fix attention on a particular case—a small isolated "cyclonic" region \( \mathcal{N} < \mathcal{N}_0 \) in which \( \nabla \cdot \mathbf{A}^0 \) is negative. From (1.2) we can imagine this as resulting from \( \nabla^2 \phi_j^0 \) not being large enough (algebraically) or from \( \nabla^2 \psi_j^0 \) being too large (algebraically) to balance the nonlinear \( \psi^0 \) terms in (1.2).
Figure 1.
Distribution of vorticity, height and temperature changes resulting from $\triangledown \cdot \mathbf{A} = -f^2$ at level 7 (250 mb) in the circular region $0 < r < 1000$ km (indicated by the open bars).

</table>

C: HEIGHT CHG IN CM
D: 100 TIMES TEMPERATURE CHG
Considering first the outer region $k > k_0$, we see from (4.9) that the two vorticity changes are equal. In this way the presumed satisfaction of (1.2) at $k > k_0$ is maintained. At the forcing level itself ($k = l$), the fact that $w_j$ and $e_{l_j} e_{l_j'}$ are both positive shows that $\nabla^2 \phi$ and $\nabla^2 \psi$ are both decreased in this outer region. In other words, the original "deficit" of $\nabla^2 \phi$ in the central region at level $l$ is dispersed laterally outward, but without destroying the balance present originally in the outer region.

At the interface $k = k_0$, $\nabla^2 \psi'$ is continuous, but $\nabla^2 \phi'$ has a discontinuity. In the central region, again at level $k = l$, $\nabla^2 \phi'$ is increased in this example, since both $\nabla^2 \lambda^o$ and $u_j$ are negative.

$\nabla^2 \psi'$ is decreased ($1 + u_j$ being positive). Thus $\nabla^2 \phi'$ and $\nabla^2 \psi'$ both participate in correcting the original imbalance in the central region at level $l$. In the central region at levels $k$ different from $l$, the sum $(\nabla^2 \phi'_k + \nabla^2 \psi'_k)$ is zero because $\sum_j e_{l_j} e_{l_j'}$ vanishes for $k \neq l$.

In a similar way, we can derive the relation

$$ (\phi - \phi^o)_k = f^2 \alpha^2 \left( \frac{\bar{F}_k}{f^2} \right)^\frac{1}{2} \left( \frac{\nabla^2 \lambda^o}{f^2} \right) \sum_j e_{l_j} e_{l_j'} (1 + u_j, w_j) $$

and also use this to evaluate $T_k = T_k (\phi'_k - \phi'_{k-1})$ at $k = 2, \ldots, 7$.

These functions have been computed using the same distribution of $\nu_k, \nu, \bar{\nu}_k$ and $\nu_k$ used for Table I, and with $\sin \Theta = 0.707$, $k_0 = (200 \text{ km} / \alpha)$ and $(\nabla^2 \lambda^o / f^2) = -1$. The results for $l = 7$ (250 mbs) are shown in figure 1. Parts (A) and (B) of figure 1 verify
the deductions discussed above. (The printed values for \( \nabla^2 \phi' / \xi^2 \) at \( \nu = \nu_0 \) in part (A) are the averages of the inner and outer solutions at \( \nu = \nu_0 \).) The lateral dispersion of negative \( \nabla^2 \phi \) at \( \ell = 7 \) from the inner to the outer region is clear. As a counterpart to this, we see that \( \nabla^2 \psi' \) in the central region at \( \ell = 7 \) is negative, and the original "excess" of \( \nabla^2 \psi \) at \( \nu < \nu_0 \), \( \ell = 7 \), is dispersed vertically in this region, since \( \nabla^2 \psi' \) is positive at \( k < \ell \) for \( \nu < \nu_0 \).

The distribution of height change \( \gamma' = \phi'/\xi \) in part (C) of figure 1 is readily understood from the distribution of \( \nabla^2 \phi' \). It corresponds to a fall in height centered at \( k = 7, x = 0 \). This leads of course to the temperature decreases shown in part (D) at \( k \leq \ell \) and temperature increases at \( k > \ell \). (Recall that \( T_k = \nu_k (\phi_k - \phi_{k-1}) \), so that \( T_\ell' = \nu_\ell (\phi_\ell' - \phi_\ell) \).

The values of \( (\delta \phi_1)^2 = (26 \text{ m}^2 \text{sec}^{-2})^2 \), \( (\delta T)^2 = (0.6 \text{ deg})^2 \) and \( (\delta v)^2 = (2.5 \text{ m/sec})^2 \) have in this case produced a ratio of geostrophic vorticity change to vorticity change of

\[
\Gamma = \left[ \frac{1}{\xi} \frac{\nabla^2 \phi'}{\nabla^2 \psi'} \right] = \left( \frac{360 \nu_1}{6345} \right)^2 = 0.318
\]

at \( x = 0, k = \ell = 7 \). In doing so we have minimized the area integral of

\[
\sum_{k=1} \nabla^2_{\phi_k^{'}} + \sum_{k=2} \beta_k \nabla^2_{\phi_k^{'}} (\phi_k^{' - \phi_{k-1}})^2 + \tau (\phi_1^{'})^2
\]

We can therefore expect \( \Gamma \) to increase if \( \nabla^2 \) is increased (\( \delta v \) decreased) and if \( \beta \) and \( \tau \) are decreased (\( \delta T \) and \( \delta \phi_1 \) increased).
This dependence is complicated. In order to provide some numerical insight into it, a series of computations have been made in which the ratio $\delta \phi / \delta T$ is kept fixed at $(26/6) \text{ m}^2 \text{sec}^{-2} \text{deg}^{-1}$, the uniformity of $\delta T$ and $\delta v$ with $k$ is retained, but both $\sin \theta$ and the ratio $(\delta T/\delta v)$ have been varied. The results can be condensed into an approximate formula:

$$
\Gamma \approx \left[ \frac{6.63 \cdot R \delta T}{2 \pi a \sin \theta \delta v} \right]^{3.11}
$$

( $a_0$ has been kept fixed at 200 km in this procedure.) $\nabla^2 \phi'$ and $\nabla^2 \psi'$ will therefore participate equally in restoring the balance equation at $x = 0, p = .25$ in this special case, when

$$
\frac{\delta T(\text{deg})}{\delta v(\text{m sec}^{-1})} = 0.48786 \sin \theta
$$

Although determined for a special case, this case of localized imbalance at $p = .25$ is realistic enough that (4.12) and (4.13) may be useful in adjusting the effects of different $\delta T$ and $\delta v$. 
5. Effect of a horizontal variation in analysis weights

The functions \( \beta' \) and \( \beta' \) represent the horizontal variation of \( \frac{\overline{e_{\mu}^2}}{\overline{e_{\mu}^2}} \) and \( \frac{\overline{e \bar{T}^2}}{\overline{e \bar{T}^2}} \), with a mean value of one. They will therefore be less than one over "oceanic" regions and greater than one over the data-rich continents and, to a considerable extent, will be quite similar to one another: \( \beta' \sim \beta' \). Using Cartesian coordinates \( x, y \), we can examine most simply the effect of this horizontal variation by considering the step function distribution

\[
\beta' = \gamma' = \begin{cases} \nu_1 : (y > 0) & \text{(Region I)} \\ \nu_2 : (y < 0) & \text{(Region II)} \end{cases}
\]

This is introduced into equations (4.1) together with a forcing function

\[
F_j = G_j \sin m y \sin (p x + \nu).
\]

\( \nu_1, \nu_2 \) and \( G_j \) are constants. \( \nu \) is a phase angle, and \( m \) and \( p \) are positive wave numbers.

The equations in both regions are the same:

\[
h_j = G_j \nu(x) \sin m y,
\]

and

\[
s_j = G_j \nu(x) \sin m y,
\]

\[
\left( \frac{d^2}{dx^2} - m^2 \right) \nu(x) - \sigma_j^2 \nu = 0.
\]
The internal boundary conditions at $x = 0$ are continuity in $h, s, \partial h/\partial x, \partial (h'/s')/\partial x$. These translate into

\[
\begin{pmatrix}
  \mu \\
  \nu \\
  \frac{d\mu}{d\kappa} \\
  \nu \frac{d\kappa}{d\kappa}
\end{pmatrix}_{\kappa = -\epsilon} = \begin{pmatrix}
  \mu \\
  \nu \\
  \frac{d\mu}{d\kappa} \\
  \nu \frac{d\kappa}{d\kappa}
\end{pmatrix}_{\kappa = +\epsilon}
\]

as $\epsilon \to 0$. Also, the solutions must be bounded at infinity:

\[
\lim_{|\kappa| \to \infty} (\mu, \nu) = \text{finite}.
\]

The solution for $\mu$ is simply the particular solution

\[
\mu = \frac{\sin (p_{\kappa} + \nu)}{p^2 + m^2 + \sigma_j^2}, \quad -\infty \leq \kappa \leq +\infty,
\]

since the boundary conditions (5.5a) and (5.5b) rule out the homogeneous solution $\exp \pm (m^2 + \sigma_j^2)x$ for $u$. The solution for $v$ is

\[
v = -\frac{\sigma_j^2}{(m^2 + p^2)(m^2 + p^2 + \sigma_j^2)} \left[ \sin (p_{\kappa} + \nu) + \frac{\nu'_{\kappa} - \nu'_{\kappa}}{\nu'_{\kappa} + \nu'_{\kappa}} \frac{p_{\kappa} m \cos \nu}{m} e^{\frac{+m\kappa}{e}} \right],
\]

with the $+$ sign taken in region II ($x < 0$) and the $-$ sign taken in region I ($x > 0$). (We consider $m > 0$.)
The \( \sin(p\psi + \nu) \) part of \( u \) and \( v \) is the solution for any completely uniform value of \( \psi' \). The introduction of the discontinuity (5.1) into \( \psi \) and \( \beta' \) therefore does not change the geopotential field \( h_j \).

But it does change the "streamfunction" field by an amount

\[
\Delta_j' = \frac{G_j \sigma_j^2}{(m^2 + p^2)(m^2 + p^2 + \sigma_j^2)} \left( \frac{\psi'' \psi'''}{\psi'' + \psi'''} \right) \frac{\mu - \nu}{m} \sin \psi x \quad (5.7)
\]

This produces a discontinuity in the \( y \)-component of velocity across the line \( x = 0 \), i.e., a vortex sheet. The discontinuity vanishes when the phase \( \nu \) equals \( \pm \pi/2 \), i.e., when the forcing function \( \sin(p\psi + \nu) \) has its maximum or minimum at \( x = 0 \). The discontinuity in \( \psi' \) does not change the vorticity field away from the line \( x = 0 \), since \( \nabla^2 \psi_j' = 0 \)

for \( x \neq 0 \). The strength of this vortex sheet is measured by the discontinuity in meridional velocity

\[
\Delta \psi_h \quad (\text{dimen}) = \lim_{\epsilon \to 0} \frac{1}{\alpha} \left[ \left( \frac{\partial \psi_j'}{\partial \psi_h} \right)_{\psi = +\epsilon} - \left( \frac{\partial \psi_j'}{\partial \psi_h} \right)_{\psi = -\epsilon} \right] \quad (5.8)
\]

\( \sqrt{h_j} \) does not change in this case only because \( \nabla^2 \psi_j' = 0 \). For more general variations in \( \psi' \), \( h_j \) will differ from its value for \( \psi'=1 \). 

\[ \boxed{} \]
Equation (5.2) is consistent with the following spatial distribution of $\nabla \cdot \mathbf{A}$:

$$
\left(\frac{\nabla \cdot \mathbf{A}}{f^2}\right)_L = Q \sin \theta \sin \left(\beta + \phi \right)
$$

(5.9)

For simplicity we set $Q$ equal to a linear increase from zero at $p = 1$ to $Q_{\text{max}}$ at $p = .25$ and a linear decrease from $Q_{\text{max}}$ at $p = .25$ to zero again at $p = 0$. $G_j$ in (5.7) then equals $(\xi a / 2\pi) \sum_j e_{ij} \sqrt{s'_j} Q_j$,

and (5.8) can be shown to equal

$$
\Delta V_h = \frac{\xi a}{(m^2 + p^2)} \text{max} \sin \theta \left(\frac{\theta'_I - \theta'_II}{\theta'_I + \theta'_II}\right) \sum L \left(\frac{\theta'_I}{\theta'_J}\right) \frac{1}{j} \sum e_{kj} e_{ij} \sigma^2_j
$$

A value of $(0.25)^2$ for $Q_{\text{max}}$ represents a moderately intense wave system.

For definiteness we locate $x = 0$ at the west coast of a continent and, in agreement with the discussion of $\beta'$ and $\beta^*$ in section 3, we choose $\beta'_I = 2$, $\beta'_II = 0.2$. By selecting $\beta = 0$ we position the wave in $\nabla \cdot \mathbf{A}$ to correspond to a "cyclonic" region of negative $\nabla \cdot \mathbf{A}$ centered one-quarter wavelength off the coast. For the nondimensional wave numbers $p$ and $q$, we assign reasonable values of

$$
p = \frac{2\pi a}{\text{east-west wavelength}} = 4\pi
$$

$$
m = \frac{2\pi a}{\text{north-south wavelength}} = 2\pi
$$

corresponding to values of $a/2$ for the east-west wavelength and $a$ for the north-south wavelength.
Values of $\Delta V$ for the above parameter values, for $\sin \theta = 0.707$, and the same $\tilde{Z}$, $\tilde{\beta}$, $\Phi$ used for Table I, are shown in Table II (at $\sin(m \gamma) = 1$). The discontinuity $\Delta V$ is equal to $2\left( \frac{V_x}{V_{x_{\gamma}}} \right) / (c_{x_{\gamma}})$ times the continuous meridional velocity $V$ at $x = 0$ due to the $\sin(\gamma \theta + \nu)$ term in (5.6b). It is therefore not large enough to change the sign of the meridional velocity from the left side to the right side of the line $x = 0$ in this example.

This suggests that it will be practical to use horizontal distributions of $\nu'$ and $\beta'$ in (3.6) or (3.11) which change suddenly—for example in oceanic areas where an overall level of $\beta' = 0.2$ is punctuated by small regions of $\beta' = 2$ centered on scattered island and ship stations.

The predominant positive sign of $\Delta V$ in Table II can be deduced from equation (3.11) and the results of section 4. In the given area, $\nabla \cdot \tilde{\alpha}$ is zero at $x = 0$ and negative to the west ($x < 0$). For uniform $\nu'$ and $\beta'$ we therefore expect a center of positive streamfunction change west of $x = 0$ and a negative center to the east of $x = 0$, giving a negative value of $\partial S/\partial \phi$ at $x = 0$. Referring to equation (3.11b),

$$\nabla \cdot \nabla S_j + \nabla \cdot \sin \phi \nabla R_j = 0,$$

we can imagine the introduction of a non-uniform $s'$ as resulting in an approximate equation:

$$\nu' \nabla^2 s_j \text{ (new)} + \nabla \cdot \sin \phi \nabla R_j = -\nu' \cdot \nabla \cdot \tilde{s} \text{ (old)}$$

The right side of this equation would be positive at $x = 0$ for the case shown in Table II.
Table II. Values of $\Delta V$ at $m y = \pi/2$. This is the discontinuity in meridional velocity produced at a west coast ($x = 0$) for a realistic forcing function $V = f^2 Q \sin(my) \sin(x)$. The continuous meridional velocity $V$ at $x = 0$ is also tabulated.

</table>
The following argument illustrates the minimization principle acting here. In the figure, let $\psi'_\max$ and $\psi'_\min$ denote the circulation change pattern for $\varphi' = \beta' = 1$. The superposition of (5.7) from non-uniform $\varphi$ acts to reduce $(\nabla \psi')^2$ over the continental area (where $\varphi'$ is large) and increase it over the oceanic area (where $\varphi'$ is small).

6. Spectral solution methods

The problem is to get solutions for $H_j$, $S_j$ and $R_j$ in equations (3.11) in which $\varphi', \beta', F_j$ are known functions and $\lambda_j$ is a known positive constant. In this section we first consider some simple iterative techniques for the simple Cartesian case of $\varphi' = \beta' = 1$ and $\sin \theta = \text{constant}$, i.e., equations (4.2) with $\varphi' = \beta' = 1$. We shall see in this section that conventional iteration methods will probably not be satisfactory, even for this simplified problem. (Stephens also experienced difficulty in this respect; see page 737 of his 1970 paper in J. Applied Meteor.).
In order to explore iterative methods most expeditiously, we shall consider that "simultaneous relaxation" is performed. That is to say, if we have an equation

\[ \nabla^2 a^{n+1} = b^n \]

for the \( n+1 \) iteration of variable \( a \) given a known value of the \( n \) iteration of variable \( b \), we obtain \( a^{n+1} \) exactly before proceeding to the next iteration. (It seems reasonable that if conventional point-by-point relaxation schemes were used on a horizontal grid, they would converge even slower than this hypothetical simultaneous procedure.) This enables us to replace the operator \( \nabla^2 \) by a simple factor, \(-n^2\), (n is roughly equivalent to the spherical harmonic wave number). We of course now have to require convergence for all \( n \) for each \( \sigma_j \).

Equations (4.2) then reduce to

\[ -n^2 h_j + n^2 a_j = -F_j, \]
\[ a_j + r_j = 0, \]
\[ -n^2 r_j + \sigma_j^2 k_j = 0. \]

The solution is

\[ h_j = \frac{F_j}{(m^2 + \sigma_j^2)}, \]
\[ a_j = -\sigma_j^2 F_j / m^2 (m^2 + \sigma_j^2), \]
\[ r_j = \sigma_j^2 F_j / m^2 (m^2 + \sigma_j^2). \]
This solution is of course not accessible to us in solving (4.2), but we can simplify our algebra here by working instead with the "error"

\[(h, s, r)_{\text{error}} = (h_j, s_j, r_j)_{\text{approx}} - (h_j, s_j, r_j)_{\text{true}}\]

These lead to the homogeneous error equations

\[-h + s = 0,\]  
\[s + r = 0,\]  
\[-n^2 r + \sigma^2 h = 0.\]

**Iteration scheme I.**

\[h^{v+1} = s^v,\]  
\[n^2 r^{v+1} = \sigma^2 h^v,\]  
\[s^{v+1} = - r^{v+1}.\]

These lead to the convergence process

\[h^{v+1} = - \frac{\sigma^2 h^v}{n^2},\]

for \(h, r,\) and \(s.\) Convergence is thereby achieved for short waves

\[n^2 > \lambda_j \sin^2 \theta.\]

Since \(\lambda_j\) varies from 100 to 32000, this scheme is unsatisfactory by itself.
By reversing the equations, we obtain

**Iteration scheme II**

\[
\begin{align*}
\mathbf{s}^{n+1} &= \mathbf{h}^n, \\
\mathbf{r}^{n+1} &= \mathbf{e}^{n+1}, \\
\sigma^2 \mathbf{h}^{n+1} &= n^2 \mathbf{r}^{n+1},
\end{align*}
\]  

(6.5a)

which understandably gives the reverse of (6.4b):

\[
\mathbf{h}^{n+1} = -\frac{n^2}{\sigma^2} \mathbf{h}^n.
\]  

(6.5b)

This converges for long waves

\[n^2 < \lambda^2 \sin^2 \theta\]  

(6.5c)

Neither this nor (6.4c) is satisfactory for all \(n\).

**Iteration scheme III**

This is a mixture of I and II:

\[
\begin{align*}
h^* &= s^*, \quad n^2 r^* = \sigma^2 h^*, \quad s^* = -r^*, \\
s^{**} &= h^*, \quad r^{**} = -s^{**}, \quad \sigma^2 h^{**} = n^2 r^{**},
\end{align*}
\]  

(6.6a)

followed by the combination

\[
\begin{align*}
\mathbf{h}^{n+1} &= \alpha \mathbf{h}^* + (1-\alpha) \mathbf{h}^{**}, \\
\mathbf{s}^{n+1} &= \beta \mathbf{e}^* + (1-\beta) \mathbf{s}^{**},
\end{align*}
\]  

(6.6b)

where \(\alpha\) and \(\beta\) are numbers between zero and 1. These produce the iteration results

\[
\begin{align*}
\mathbf{h}^{n+1} &= -\frac{n^2(1-\alpha)}{\sigma^2} \mathbf{h}^n + \alpha s^n, \\
\mathbf{s}^{n+1} &= (1-\beta) \mathbf{h}^n - \frac{\sigma^2}{n^2} \beta s^n.
\end{align*}
\]  

(6.6c)
The iteration eigenvalue \( \mu \) for this process satisfies the quadratic
\[
\mu^2 + \left[ (1-\alpha) \frac{m^2}{\sigma^2} + \beta \frac{m^2}{\sigma^2} \right] \mu + (\beta - \alpha) = 0,
\]
with solutions
\[
\mu = \left( 1-\alpha \right) N + \frac{\beta}{N} \pm \sqrt{\left[ \left( 1-\alpha \right) N + \frac{\beta}{N} \right]^2 + 4(\alpha - \beta)} \right]^{1/2}.
\]
(6.6d)

N stands here for \( n^2/\sigma^2 \), a quantity which effectively varies from almost zero to a very large number.

For fixed \( \alpha \) and \( \beta \) the radicand has a minimum with respect to \( N \) at \( N^2 = \beta/(1-\alpha) \), this minimum value being \( 4\alpha(1-\beta) \). The square root is therefore real. Since \( (1-\alpha)N + \beta/N \) is positive, the convergence criterion is
\[
\mu_{\text{max}} = \frac{1}{2} \left\{ (1-\alpha)N + \frac{\beta}{N} + \sqrt{\left[ (1-\alpha)N + \frac{\beta}{N} \right]^2 + 4(\alpha - \beta)} \right\} < 1
\]
for all \( N \). For small \( N \),
\[
\mu_{\text{max}} = \frac{\beta}{N} + \frac{N\alpha(1-\beta)}{\beta} + O(N^3)
\]
For large \( N \),
\[
\mu_{\text{max}} = (1-\alpha)N + \frac{\alpha(1-\beta)}{(1-\alpha)N} + O(N^{-3}).
\]
The requirement that \( \beta \) be small and that \( 1-\alpha \) be small suggests that we choose \( \beta = 1-\alpha \). This gives the simpler condition
\[
\mu_{\text{max}} = (1-\alpha)Z + \sqrt{(1-\alpha)^2Z^2 + 2\alpha - 1}
\]
(6.6e)
where
\[
Z = \frac{1}{2} \left( N + \frac{1}{N} \right) > 1,
\]
\[
N = \frac{m^2}{\lambda_j \sin^2 \theta}
\]
The large range in $\frac{m^2}{\sin^2\theta}$ means that $Z$ can be very large, and the only hope for satisfying (6.6e) is to have $\alpha$ close to 1. However, $\mu_{\text{max}}$ equals one for $\alpha=1$ and $\frac{\mu_{\text{max}}}{\theta_{\text{c}}}$ at $\alpha=1$ equals $1-Z$, which is less than zero. Therefore $\mu_{\text{max}}$ will be greater than one for $\alpha$ slightly less than one. This scheme will not work.

An only slightly more successful scheme is the following.

**Iteration scheme IV**

\[
\begin{align*}
    v' &= s \\
    r^* &= (\sigma^2/n^2)h' \\
    s^* &= -r' \\
    r^{**} &= -s' \\
    h^* &= (n^2/\sigma^2)r' \\
    s^{**} &= h^* = (n^2/\sigma^2)r'
\end{align*}
\]

followed by

\[
\begin{align*}
    \Delta^{\nu+1} &= \alpha \Delta^\nu + (1-\alpha) \Delta^{**} \\
    \Delta^{**} &= \alpha \Delta^\nu + (1-\alpha) \Delta^{**}
\end{align*}
\]

This leads to the iteration scheme

\[
\Delta^{\nu+1} = -\left\{\frac{[\alpha - (1-\alpha)N]^2}{N}\right\} \Delta^{\nu-1}
\]

where $N$ again equals $n^2/\sigma^2$. The convergence criterion is

\[
[\alpha(1+N)-N]^2 < N
\]
For a fixed $\alpha$, $N$ must lie between

$$N_1(\alpha) = \frac{1 + 2\alpha - 2\alpha^2 - \sqrt{1 + 4\alpha - 4\alpha^2}}{2(1 - \alpha)^2}$$

and

$$N_2(\alpha) = \frac{1 + 2\alpha - 2\alpha^2 + \sqrt{1 + 4\alpha - 4\alpha^2}}{2(1 - \alpha)^2}$$

in order to have convergence. The values of $N_1$ and $N_2$ are as follows, $\varepsilon$ being a small quantity:

a) $\alpha = \varepsilon \quad N_1 = \frac{\varepsilon}{2} \quad N_2 = 1 + \frac{\varepsilon}{2}$

b) $\alpha = \frac{1}{2} \quad N_1 = \frac{3 - 2\sqrt{2}}{2} \approx 0.17 \quad N_2 = 3 + 2\sqrt{2} \approx 5.83$

c) $\alpha = 1 - \varepsilon \quad N_1 = 1 - \frac{\varepsilon}{2} \quad N_2 = \frac{1}{\varepsilon^2} + \frac{2}{\varepsilon} - 3 + \frac{\varepsilon}{2}$

$N$ is equal to $m^2(\lambda_j \sin \theta)^{-1} \sim 2m^2/\lambda_j$.

For $j = 1$ and $12$ we have then, with $n_{\text{min}} = 1$, the following ranges for $N$:

$$j = 1 \quad 0.02 \leq N < \infty$$

$$j = 12 \quad 0.000067 \leq N < \infty$$

Both $j = 1$ and $j = 12$ will have their lower limit $N_1$ satisfied only by small $\alpha$ ($\alpha = \varepsilon$) but the upper limit $N_2$ will not be satisfied. This method is therefore unsatisfactory also.

An iterative method to solve even the simplified system (6.1) does not seem possible. We therefore turn to a more direct method.
7. Use of spherical harmonics

We consider now the complete system (3.11), dropping the $j$ subscripts for simplicity:

$$\nabla^2 H - \nabla \cdot \sin \theta \nabla S = - F,$$

$$\nabla \cdot \nabla H + \nabla \cdot \sin \theta \nabla R = 0,$$

$$\nabla^2 R + \lambda \beta' H = 0.$$

We first rewrite this to put all variable $\gamma'$ and $\beta'$ effects on the right side:

$$\nabla^2 H - \nabla \cdot \sin \theta \nabla S = - F,$$  \hspace{1cm} (7.1)

$$\nabla^2 S + \nabla \cdot \sin \theta \nabla R = \nabla \cdot (1-\gamma') \nabla S,$$  \hspace{1cm} (7.2)

$$\nabla^2 R + \lambda H = \lambda (1-\beta') H.$$  \hspace{1cm} (7.3)

The iteration process will consist of using the previous iterates $S^\gamma$ and $H^\gamma$ (initially zero) for the right sides of (7.2) and (7.3), and determining $H^{\gamma+1}$, $S^{\gamma+1}$ and $R^{\gamma+1}$ from the left side of (7.1)-(7.3). [The process for the special case $\gamma' = \beta' = 1$ explored in section 6 would not be iterative, and therefore not subject to those convergence problems.]

We use the normalized spherical harmonics to expand these fields, for example

$$Y_n^m = P_n^m e^{im\lambda},$$

$$H = \sum_{m,n} H_n^m Y_n^m.$$  \hspace{1cm} (7.4)
This is done for the three unknowns $H, S, R$ on the left sides of (7.1)-(7.3). ($S^0_0$ and $R^0_0$ are defined to be zero.) Let us also consider that the right sides of (7.1)-(7.3) have also been expanded in spherical harmonics, perhaps by a transform technique, for a given $\nu$ iteration.

The operator $V^2$ on (7.4) produces the well-known result

$$\nabla^2 H = - \sum m(m+1) H^m_{-m} Y^m_m.$$

The operator $\nabla \sin \theta \nabla S$ however becomes

$$\nabla \sin \theta \nabla S = \sin \theta \nabla^2 S + \cos \theta \partial S/\partial \theta$$

$$= \nu \nabla^2 S + (1-\nu^2) \partial S/\partial \nu$$

so that

$$\nabla \sin \theta \nabla S = \sum S^m_m \left[ -m(m+1) \frac{\partial Y^m_m}{\partial \nu} + (1-\nu^2) \frac{\partial Y^m_m}{\partial \nu} \right]$$

(We have introduced the conventional notation $x = \sin \theta$ at this point.)

Using the relations (8.5.3), (8.5.4) and (8.14.13) in Abramowitz and Stegun, we can show that

$$-m(m+1) \frac{\partial Y^m_m}{\partial \nu} + (1-\nu^2) \frac{\partial Y^m_m}{\partial \nu} = -m(m+2) a^m_{m+1} Y^m_{m+1} - (m^2-1) a^m_m Y^m_{m-1}$$

(7.5)

in which

$$a^m_m = \left[ \frac{m^2 - m^2}{4m^2 - 1} \right]^{1/2}, \quad a^m_{m} = 0.$$

(7.6)

(Note that $a^0_0$ is not needed, since $S^0_0$ and $R^0_0$ are zero.)
For simplicity let us now consider only a single zonal wave number $m$ and temporarily suppress the $m$ superscripts and subscripts. Equations (7.1)-(7.3) are

\[
- \sum_{n=0}^{N_m} n(m+1) H_n P_n + \sum_{n=0}^{N_m} W_n [n(m+2) a_{n+1} P_{n+1} + (m^2-1) a_n P_{n-1}] = -\sum_{n=0}^{N_m} F_n P_n,
\]

\[
- \sum_{n=0}^{N_m} n(m+1) S_n P_n - \sum_{n=0}^{N_m} W_n [n(m+2) a_{n+1} P_{n+1} + (m^2-1) a_n P_{n-1}] = \sum_{n=0}^{N_m} A_n P_n,
\]

\[
\sum_{n=0}^{N_m} [2 H_n - m(m+1) R_n] P_n = \sum_{n=0}^{N_m} B_n P_n
\]

where $F_n$, $A_n$, and $B_n$ denote the expansion coefficients of the right sides of (7.1)-(7.3). Collecting corresponding coefficients now gives us three equations for $n = m, m+1, \ldots, N_m-1, N_m$:

\[
-m(m+1) H_n + (m^2-1) a_n S_{n-1} + n(m+2) a_{n+1} S_{n+1} = -F_n, \tag{7.7a}
\]

\[
m(m+1) S_n + (m^2-1) a_n R_{n-1} + n(m+2) a_{n+1} R_{n+1} = -A_n, \tag{7.7b}
\]

\[
2 H_n - m(m+1) R_n = B_n. \tag{7.7c}
\]

The $a_n$ terms in (7.7a) and (7.7b) disappear for $n = m$. At $n = N_m$, the $S$ and $R$ terms in (7.7a) and (7.7b) vanish. (We can simply define $a_n^m = 0$ for $m > N_m$.) Elimination of $H_m$ reduces this to
Elimination of $S_n$ is now convenient. If we define

$$b_n = \frac{(m-1)(m+1)}{m} a_n = \frac{m^2-1}{m} \sqrt{\frac{m^2-m^2}{4m^2-1}}$$

the result is an equation for $R_n$:

$$b_n b_{n-1} R_{n-2} + \left[ \frac{m b_n^2}{m-1} + \frac{(m-1)b_{n-1}^2}{m+2} + \frac{m^2(m+1)^2}{\lambda} \right] R_n + b_{n+1} b_{n+2} R_{n+2} = F_n - \frac{a_n(m+1)}{\lambda} B_n - \left[ \frac{b_n}{m-1} A_{n-1} + \frac{b_{n+1}}{m+2} A_{n+1} \right]$$

(Note that $b_n^2/(m-1)$ vanishes for $n = 1$ and that $b_n$ vanishes for $n = m$ and for $n > N_m$). The matrix multiplying the column vector $R_n$ ($n = m, m+1, \ldots, N_m$) is symmetric, with entries only along the principal diagonal and the upper and lower diagonals twice removed from the main diagonal. (The latter feature reflects the fundamental separation of $p_n^m$ into even and odd polynomials.)

Having solved for $R_n$ from (7.10), we find $S_n$ from (7.8b) and $H_n$ from (7.7c). These are the new iterates $H_{n+1}$ and $S_{n+1}$. The right sides of (7.2) and (7.3) can then be reevaluated with the new $H$ and $S$, and the process repeated.

An interesting question is the truncation limits to be assigned to $m$ and $N_m$ in the expansions (7.4). These limits should be large enough to
include the information content in the original forcing field \( \nabla \cdot A^0 \), but they must also be large enough to properly reflect the \( \gamma' \) and \( \beta' \) distribution. Numerical experimentation will undoubtedly be necessary to resolve this question.

The system of equations (7.10) can be solved directly as follows. Consider separately the equations for \( n = m, m+2, m+4, \ldots \) and the independent set \( n = m+1, m+3, \ldots \). Each set can be written as

\[
\begin{align*}
\alpha_{1} \nu_{1} + \alpha_{2} \nu_{2} & = b_{1} \\
\alpha_{1} \nu_{1} + \alpha_{2} \nu_{2} + \alpha_{3} \nu_{3} & = b_{2} \\
\vdots & \quad \vdots \\
\alpha_{k-1} \nu_{k-1} + \alpha_{k} \nu_{k} + \alpha_{k+1} \nu_{k+1} & = b_{k} \\
\alpha_{k-2} \nu_{k-2} + \alpha_{k-1} \nu_{k-1} + \alpha_{k} \nu_{k} & = b_{k-1} \\
\alpha_{k-1} \nu_{k-1} + d_{k} \nu_{k} & = b_{k}
\end{align*}
\]

by using an obvious notation. We look for a solution of the form

\[
\nu_{k} = -A_{k} \nu_{k+1} + B_{k}, \quad k = k-1, k-2, \ldots, 2, 1.
\]

Substituting into the general form (7.11c) produces the coefficient scheme for \( k = 2, \ldots, k-1 \):

\[
A_{k} = \frac{a_{k}}{d_{k} - \alpha_{k-1} A_{k-1}}
\]
\[ B_k = \frac{b_k - B_{k-1}}{a_k - a_{k-1} A_{k-1}}. \]  

(7.13b)

(7.11a) produces the starting values for this scheme:

\[ A_i = \frac{a_i}{d_i}, \quad B_i = \frac{b_i}{d_i}. \]  

(7.13c)

(7.13d)

Having computed \( A_1, \ldots, A_{K-1} \) and \( B_1, \ldots, B_{K-1} \) [which have used all equations except (7.11e)], we determine \( \nu_k \) by using (7.12) and (7.11e),

\[
\nu_{k-1} = -A_{k-1} \nu_k + B_{k-1},
\]

\[
a_{k-1} \nu_{k-1} = -d_k \nu_k + b_k,
\]

to determine \( \nu_k \):

\[
\nu_k = \frac{b_k - a_{k-1} B_{k-1}}{d_k - a_{k-1} A_{k-1}}.
\]

(7.14)

(7.12) then produces successively \( \nu_{k-1}, \nu_{k-2}, \ldots, \nu_2, \nu_1 \).

8. **Initial field of divergence**

The previous seven sections have been devoted to determining mutually balanced fields of a streamfunction and geopotential. We now supplement this with a quasi-geostrophic determination of an initial field of divergence. The quasi-geostrophic system to be used is one of the simpler
versions defined by Lorenz (Tellus, 1960, p. 364), in which the Coriolis parameter is fully variable. (The following description is for the entire globe, but a restriction to the Northern Hemisphere with the usual symmetry conditions is easily obtained.)

The equations are written in the following nondimensional variables and symbols:

\[ p = \text{pressure} \div (100 \text{ cb}) \]
\[ t = \text{time} \times 2\Omega \]
\[ \nabla = \text{horizontal gradient} \times a \]
\[ \psi = \text{streamfunction} \div (2\Omega a^2) \]
\[ \phi = \text{variable geopotential} \div (4\Omega^2 a^2) \quad (8.1) \]
\[ Z = -\ln p \]
\[ W = dZ/dt \]
\[ \bar{T} = \text{standard atmosphere temperature} \]
\[ \frac{\partial \phi}{\partial t} = \text{velocity potential} \div (2\Omega a^2), \text{ i.e.} \]
\[ \frac{\partial \phi}{\partial t} = \nabla (\partial \phi/\partial p) \]
\[ \chi = \text{sine (latitude)} \]

The equations consist of the vorticity equation,

\[ \nabla^2 \frac{\partial \psi}{\partial t} + \nabla \cdot \nabla \frac{\partial \phi}{\partial p} = -\frac{\hat{k}}{\Omega} \times \nabla \psi \cdot \nabla (\phi + \partial^2 \psi) = -A, \quad (8.2) \]

and the linear balance equation,

\[ \nabla \cdot \nabla \frac{\partial \psi}{\partial t} = \nabla^2 \frac{\partial \phi}{\partial t}, \quad (8.3) \]
the simplified first law (combined with the hydrostatic equation),

\[
\frac{\partial}{\partial x} \frac{\partial}{\partial t} + S \nu \frac{\partial}{\partial x} \psi = \frac{\kappa \psi}{\theta \Omega^2 a^2} - \hat{k} \times \nabla \psi \cdot \nabla^2 \phi = B, \tag{8.4}
\]

the continuity equation,

\[
\rho \nu = \nabla^2 \psi, \tag{8.5}
\]

the upper boundary condition at \( p = p_{\text{top}} \),

\[
\nu = 0, \quad \nabla^2 \psi = 0, \tag{8.6}
\]

and the bottom boundary condition at \( p = 1 \):

\[
\nu = \frac{q}{2a R} \nu = C. \tag{8.7}
\]

In (8.4), \( S \) is the static stability function

\[
S = S(z) = \frac{H^2 N^2}{4 \Omega^2 a^2} = \left( \frac{R}{g} \right)^2 \frac{\rho}{\rho_g} \frac{\partial z}{\partial z} \frac{1}{4 \Omega^2 a^2}. \tag{8.8}
\]

(\( S \) varies from about 0.01 to 0.03.) \( q \) is the heating rate per unit mass. \( \nu \) in (8.7) is the vertical velocity (dimensional) at the bottom due to orography and friction:

\[
\nu (\text{dim}) = 2 \nu \left[ \frac{\hat{k} \times \nabla \psi \cdot \nabla \phi}{\Phi} + D \nabla^2 \psi \right]. \tag{8.9}
\]

\( z_0 \) is the (dimensional) ground height and \( D \) is a length \( \approx 150 \) meters.

Equation (8.7) should really have a term:

\[
\frac{4 \Omega^2 a^2}{R} \frac{\partial \phi}{\partial t} = \mu \frac{\partial^2 \phi}{\partial t}, \quad \mu \approx 10. \tag{8.10}
\]
added to the left side. This term is negligible, however, except possibly for the very longest horizontal and vertical wave lengths.

Our goal is to determine $\partial X/\partial p$. We shall assume that the vorticity advection term $A$ in (8.2), the temperature advection and heating term $B$ in (8.4), and the vertical velocity term $C$ in (8.7) are known functions, being determined from the balanced fields of $\phi$, $\psi$ and (in the case of $w$) from the known orographic height.

The bottom of the atmosphere will be set at the constant value $p = 1$ (100 cb), since this uniformity is required by the quasi-geostrophic system. The pressure surfaces on which $A$ and $B$ are most directly computed are set by the standard pressure surfaces on which $\phi$ and $\psi$ were computed in the variational analysis ($p = 1, .85, .7, .5$, etc.). The logical vertical structure of the variables, however, has both $X$ and $W$ at a series of pressure levels running from $p = 1$ to $p_{\text{top}}$, with the other variables $\partial\psi/\partial t$ and $\partial\phi/\partial t$ at interleaved values of $p$; this arrangement conflicts with the vorticity advection term being specified at $p = 1$. We therefore assume that $A$ and $B$ can be defined by vertical interpolation at a new convenient set of pressure levels.

The convenient levels are defined by $K$ uniform increments ($\Delta$) in $Z = -\ln p$:

$$Z_k = (k-1)\Delta; \ k = 1, \ldots, K+1,$$
$$Z_1 = 0,$$
$$Z_{K+1} = -\ln(p_{\text{top}}) = K\Delta = Z_{\text{top}}$$

$\Delta = \frac{Z_{\text{top}}}{K}$

K here need not equal the K used in sections 1-7.
At the $Z_k$ levels, the value of $p$ is $p_k$:

$$p_k = e^{-Z_k} = e^{-A} p_{k-1} = r^2 p_{k-1},$$

$$r = e^{-A/2}.$$  

Each $p_k$ is a uniform fraction $r^2$ of the preceding $p_{k-1}$. Each $p_{\text{top}}$, it should be noted, cannot equal zero in this system. The computational convenience of this coordinate system is however great enough to accept this limitation.

At these levels we define the unknowns $X_k$ and $W_k$ and (for $k = 2, \ldots, K$) the known temperature term $B_k$ and stability $S_k$). Intermediate levels are defined at the average values of $Z$, and carry with them the unknowns $\psi/\partial t, \partial \phi/\partial t$ and the known quantity $A$. The $k$ subscript is used as shown in this diagram:
\[ z_{k+1} = x_{k+1} = w_{k+1} = 0 \]
\[ \left( \frac{\partial \psi}{\partial x} \right)_k, \left( \frac{\partial \psi}{\partial t} \right)_k ; A_k \]
\[ z_k = x_k, w_k ; B_k, S_k \]

\[ z_{k+1} = x_{k+1}, w_{k+1} ; B_{k+1}, S_{k+1} \]
\[ \left( \frac{\partial \psi}{\partial x} \right)_k, \left( \frac{\partial \psi}{\partial t} \right)_k ; A_k \]
\[ z_k = x_k, w_k ; B_k, S_k \]
\[ \left( \frac{\partial \psi}{\partial x} \right)_{k-1}, \left( \frac{\partial \psi}{\partial t} \right)_{k-1} ; A_{k-1} \]
\[ z_{k-1} = x_{k-1}, w_{k-1} ; B_{k-1}, S_{k-1} \]

\[ z_2 = x_2, w_2 ; B_2, S_2 \]
\[ \left( \frac{\partial \psi}{\partial x} \right)_1, \left( \frac{\partial \psi}{\partial t} \right)_1 ; A_1 \]
\[ z_1 = x_1, w_1 = C \]

\( p \) at the intermediate levels, for example, at the level corresponding to \( (\partial \psi/\partial t)_h \), is denoted by

\[ r_{h+1/2} = e^{\frac{1}{2}(z_h + z_{h+1})} = \sqrt{p_h p_{h+1}} \]

\[ = 2 \sqrt{p_h} \]
Our first manipulation is to express (8.4) at \( k = 2, \ldots, K \) with the obvious finite-difference equivalent of \( \partial (\partial \psi / \partial t) \partial Z \), apply the operator \( \Delta \nabla^2 \) to it, and then replace \( \partial \psi / \partial t \) by \( \partial \psi / \partial t \) from (8.3). This result is \( (k = 2, \ldots, K) \):

\[
\nabla \cdot \n \left[ \left( \frac{\partial \psi}{\partial t} \right)_k - \left( \frac{\partial \psi}{\partial t} \right)_{k-1} \right] + \Delta S_k \nabla^2 W_k = \Delta \nabla^2 B_k. \tag{8.15a}
\]

If we define the inverse Laplace operator by \( \mathcal{L} \), so that (8.5) can be expressed as

\[
X = \mathcal{L} W, \tag{8.15b}
\]

the vorticity equation can be written \( (k = 1, \ldots, K) \)

\[
\nabla^2 \frac{\partial \psi}{\partial t}_k - \nabla \cdot \nabla \mathcal{L} \left[ \frac{p_{k+1} W_{k+1} - p_k W_k}{\Delta p_{k+1/2}} \right] = A_k. \tag{8.15c}
\]

We now difference this in the vertical. At the same time we define new variables, so that a symmetric system will emerge. The new variables are

\[
\begin{align*}
\nabla \cdot \nabla & = \nabla \cdot \n \mathcal{L} W_k, \\
U_k & = \mathcal{L} \left[ \left( \frac{\partial \psi}{\partial t} \right)_k - \left( \frac{\partial \psi}{\partial t} \right)_{k-1} \right], \tag{8.15d}
\end{align*}
\]

where \( v_k \) and \( u_k \) are functions only of \( k \), and are to be determined for our convenience. The result can be written \( (k = 2, \ldots, K) \)

\[
\left[ \frac{\nabla \cdot \n \mathcal{L} W_k}{\Delta \mathcal{L} \left[ \left( \frac{\partial \psi}{\partial t} \right)_k - \left( \frac{\partial \psi}{\partial t} \right)_{k-1} \right]} \right] \nabla \cdot \n \mathcal{L} W_k + \nabla^2 \mathcal{L} W_k = \frac{\mathcal{L} W_k}{S_k} \nabla^2 B_k, \tag{8.16a}
\]
A convenient choice is

\[ \nu_k = \left( \frac{p_k}{s_k} \right)^{1/2}, \quad \omega_k = \left( \frac{p_k}{s_k} \right)^{1/2} / \Delta. \]  

This leads to the two equations \((k = 2, \ldots, K)\)

\[ \nabla \cdot \nu \nabla U_k + \nabla^2 V_k = \left( \frac{p_k}{s_k} \right)^{1/2} \nabla^2 B_k, \]  

\[ \nabla^2 U_k + \frac{\nabla \cdot \nu \nabla \nu}{\Delta^2} \left[ -\frac{V_{k+1}}{\sqrt{s_k s_{k+1}}} + (a + \frac{1}{2}) \frac{V_k}{s_k} - \frac{V_{k-1}}{\sqrt{s_k s_{k-1}}} \right] = -\left( \frac{p_k}{s_k} \right)^{1/2} \frac{A_k - A_{k-1}}{\Delta}. \]

\(k\) in these equations runs from 2 to \(K\). In (8.18b), the term \(V_{k+1}\) for \(k = K\) vanishes, since \(W_{K+1} = 0\). At the lower limit, the \(V_{k-1}\) term for \(k = 2\) is

\[ -\frac{\nabla \cdot \nu \nabla \nu V_1}{\Delta^2 \sqrt{s_1 s_2}} = -\frac{1}{\Delta^2 \sqrt{s_2}} \nabla \cdot \nu \nabla \nu W_1. \]  

(Note the cancellation of the hitherto undefined number \(S_1\).) Since \(W_1\) is equal to the known quantity \(C\) in (8.7), we can remove this term to the right side of (8.18b) when \(k = 2\).
The bracketed operator on \( V_k \) in (8.18b) is now a symmetric tridiagonal matrix \( D_{k\ell} \) \((k, \ell = 2, \ldots, K)\):

\[
D_{k\ell} = \begin{pmatrix}
\delta_2 - a_2 & 0 & & \\
- a_2 & d_3 - a_3 & & \\
& - a_3 & d_3 & \\
& & & 0
\end{pmatrix}
\]

(8.19)

\[
d_k = (\lambda + \frac{1}{\mu}) \frac{1}{\Delta^2 s_k} , \quad a_k = \frac{1}{\Delta^2 \sqrt{s_k s_{k+1}}}
\]

It will have \( K-1 \) positive eigenvalues \( \lambda_j \) and orthonormal eigenvectors \( \epsilon_{kj} \) \((k, j = 2, \ldots, K)\).

\( \vee \) The determinant of \( D \) is equal to \( \sinh(K\Delta/2) \div [\Delta^{2(K-1)} S_2 S_3 \cdots S_K \sinh(\Delta/2)] \), so that \( \lambda \) does not equal zero. The eigenvectors of \( D \) do not have the large amplitude variation with \( k \) that is present in the variational matrix \( B_{k\ell} \) (Table I). In the special case of uniform \( S_k \) (i.e., an isothermal atmosphere), the eigenvalues of \( D \) are \( \lambda_j = (2/\Delta^2 s) [\cosh(\Delta/2) - \cosh(\pi j/\Delta/2)] \), and the eigenvectors are simply \( \epsilon_{kj} = (2/\mu) \sin [(h-1)(j-1)\pi/\Delta] ; j = 2, \ldots, K ; h = 2, \ldots, K \).
We expand the unknowns and the known right sides in these eigen-vectors as follows:

\[ u_j = \sum_{k=2}^{K} e_{kj} U_k, \]
\[ v_j = \sum_{k=2}^{K} e_{kj} V_k, \]
\[ \beta_j = \sum_{k=2}^{K} e_{kj} \left( \frac{p_k}{s_k} \right)^{\nu_2} \nabla^2 B_k, \]
\[ \alpha_j = \sum_{k=2}^{K} e_{kj} \left( \frac{p_k}{s_k} \right)^{\nu_2} \left( \frac{A_k-A_{k-1}}{\Delta} \right) + \frac{e_{k,j} \nabla \cdot \nabla \cdot \nabla C}{\Delta^2 \sqrt{s_2}} \]  

(The special term in \( \alpha_j \) comes from (8.18c).) We thereby arrive at \( K-1 \) pairs of two dimensional equations \((j = 1, \ldots, K-1)\):

\[ \nabla \cdot \nabla u_j + \nabla^2 v_j = \beta_j, \]
\[ \nabla^2 u_j + \lambda_j \nabla \cdot \nabla \nabla v_j = \alpha_j. \]  

We solve these using spherical harmonics. Before we do so, we note that the desired result is the field of \( \frac{\partial \psi}{\partial t} \)--the nondimensional velocity potential--at the levels in diagram (8.13) corresponding to \( \frac{\partial \psi}{\partial t} \). Using (8.14), (8.15b), (8.15d) and (8.17, we find, in succession,
\[ \left( \frac{\partial X}{\partial t} \right)_k = - \left( \frac{1}{4} \frac{\partial X}{\partial z} \right)_k = \frac{1}{\Delta} \left[ \left( \frac{p_k}{p_{k+1}} \right)^2 W_k - \left( \frac{p_k}{p_{k+1}} \right)^2 W_{k+1} \right] \]

\[ = \frac{1}{\Delta} \left[ \frac{Z V_k}{\sqrt{s_k p_{k+1}}} - \frac{Z V_{k+1}}{\sqrt{s_{k+1} p_k}} \right] \tag{8.22} \]

It is therefore somewhat more convenient to expand \( Z v_j \) rather than \( v_j \). We now suppress the \( j \) subscript for convenience and expand as follows:

\[ m_j = \sum_{m} m_m Y_{nm} \]

\[ Z v_j = \sum_{m} v_{nm} Y_{nm} \]

\[ (\alpha, \beta)_n = \sum_{m} (\alpha_{nm}, \beta_{nm}) Y_{nm} \tag{8.23} \]

where \( Y_{n}^m \) are the normalized spherical harmonics. By using relation (7.5), we obtain two equations:

\[ - \left[ m b_m \mu_{m-1} + (m+1) b_{m+1} \mu_{m+1} \right] + \lambda^2 (m+1)^3 \mu_m = \beta_m, \]

\[ m (m+1) \mu_m + \lambda \left[ m b_m \nu_{m-1} + (m+1) b_{m+1} \nu_{m+1} \right] = -\alpha_m, \]

where \( b_n \) is given by (7.9), and we have suppressed the \( m \) superscript. These can be collapsed into one equation for \( v \):

\[ b_m b_{m-1} \nu_{m-2} + \left[ \frac{m b_m^2}{(m-1)} + \frac{(m+1) b_{m+1}^2}{(m+2)} + \frac{\lambda^2 (m+1)^3}{2} \right] \nu_m \]

\[ + b_{m+1} b_{m+2} \nu_{m+2} = \frac{1}{\lambda} \left[ \beta_m - \frac{b_m}{(m-1)} \alpha_{m-1} - \frac{b_{m+1}}{(m+2)} \alpha_{m+1} \right]. \tag{8.24} \]
This can be solved for \( v_n \) by the method sketched at the end of section 7. 

For use in (8.22) is then obtained by reversing (8.20):

\[
\mathcal{L} V_k = \sum_{j=2}^{K} e_{kj} \mathcal{L} V_j
\]

\[
= \sum_{j=2}^{K} e_{kj} \sum_{m_1, m_2} \mathbf{v}_m^{m_1} (\lambda, \nu) \mathbf{v}_m^{m_2} (\lambda, \nu)
\]

(8.25)

The dimensional divergent velocity is then given by

\[
\vec{u}_{\text{div}} (\text{dim}) = 2 \alpha \Delta a \left[ \nabla \left( \frac{\partial X}{\partial \psi} \right) \right]_{\text{non-dim}}
\]

(8.26)

A final remark concerns the part of \( \nabla \cdot \vec{u} \) that is due to friction—the 2ND \( \nabla^2 \psi \) term in (8.9). The boundary treatment underlying (8.9) assumes that frictional effects below \( p = 1 \) have caused a convergence pattern in a boundary layer below \( p = 1 \). The divergence field given by (8.26) does not include this boundary field, only the geostrophic response to it above \( p = 1 \). Therefore, when \( \vec{u}_{\text{div}} \) from (8.26) is added to the initial field of a primitive equation model (i.e., the goal of section 8), the lowest layer or layers in that model should also have added to them this implied low-level frictional convergence field. If \( \Delta p \) (cb) denotes the (local) thickness of this bottom model layer, the added frictional divergence in that layer should be

\[
\nabla \cdot \vec{u} = - \left( \frac{\rho}{\Delta p} \right) \left( \frac{P_{sfc}}{100} \right) \omega,
\]
where \( w \) is the same horizontal field as that used in (8.7). The second factor allows roughly for the loss of the lower level part of (8.26) in regions where \( p_{sfc} \) is significantly less than 100 cb.
